

Overview

XQuery is *the* language for querying XML data

XQuery for XML is like SQL for databases

XQuery is built on XPath expressions

XQuery is supported by all major databases

XQuery is a W3C Recommendation

XQuery is a language for finding and extracting elements and attributes from XML documents.

Here is an example of what XQuery could solve:

"Select all CD records with a price less than \$10 from the CD collection stored in cd_catalog.xml"

FLWOR Expressions

For	Selects a sequence of nodes
Let	Binds a sequence to a variable
Where	Filters the nodes
Order by	Sorts the nodes
Return	What to return (gets evaluated once for every node)

Example:

```
for $x in doc("books.xml")/book
where $x/price>30
order by $x/title
return $x/title
```

The For Clause

The For Clause (cont)

```
return <test> x={$x} and y={$y} </test>
```

Returns

```
<test>x=10 and y=100</test>
<test>x=10 and y=200</test>
<test>x=20 and y=100</test>
<test>x=20 and y=200</test>
```

The Let Clause

This

```
let $x := (1 to 5)
return <test> {$x} </test>
```

Returns

```
<test>1 2 3 4 5</test>
```

The let clause allows variable assignments and it avoids repeating the same expression many times. The let clause does not result in iteration.

The Where Clause

This

```
where $x/price>30 and $x/price<100
```

Returns Nodes only where the price is between 30 and 100

The where clause is used to specify one or more criteria for the result.

The order by Clause

This

```
for $x in doc("books.xml")/book
order by $x/category, $x/title
return $x/title
```

Returns

```
<title lang="en">Harry Potter </title>
<title lang="en">Everyday Italia </title>
<title lang="en">Learning XML</title>
<title lang="en">X Query Kick Start</title>
```

The order by clause is used to specify the sort order of the result.

To loop a specific number of times in a for clause, you may use the **to** keyword.

This

```
for $x in (1 to 5)
return <te st> {$x }</ tes t>
```

Returns

```
<te st> 1</ tes t>
<te st> 2</ tes t>
<te st> 3</ tes t>
<te st> 4</ tes t>
<te st> 5</ tes t>
```

To count the iteration use the **at** keyword

This

```
for $x at $i in doc("bo oks.xml")/ boo kst ore /bo o
k/ title
return <bo ok> {$i}. {data( $x) }</ boo k>
```

Returns

```
<bo ok>1. Everyday Italia n</ boo k>
<bo ok>2. Harry Potter </b ook>
<bo ok>3. XQuery Kick Start< /bo ok>
<bo ok>4. Learning XML</b ook>
```

it is also allowed with more than one expression in the for clause. Use comma to separate each in expression.

This

```
for $x in (10,20), $y in (100,200)
```

The Return Clause

This

```
for $x in doc("books.xml")/ bookstore /book
return $x/title
```

Returns

```
<title lang="en">Everyday Italia n</ title>
<title lang="en">Harry Potter </title>
<title lang="en">X Query Kick Start</title>
<title lang="en">Learning XML</title>
```

The return clause specifies what is to be returned.

XQuery Basics

doc()	doc("books.xml")	Used to open a file
Path Expressions	doc("books.xml")/bookstore/book/title	Used to navigate through elements in an XML document
Predicates	doc("books.xml")/bookstore/book[price<30]	Used to limit the extracted data

XQuery Basic Syntax Rules

XQuery is case-sensitive

XQuery elements, attributes, and variables must be valid XML names

An XQuery string value can be in single or double quotes

An XQuery variable is defined with a \$ followed by a name, e.g. \$bookstore

XQuery comments are delimited by (: and :)
(: XQuery Comment :)

Path Expressions vs. FLWOR Expressions

Path Expression

```
doc("books.xml")/ bookstore /book[ price<30 ] /title
```

FLWOR Expression

```
for $x in doc("books.xml")/bookstore/book
declare function local: min Price($p as xs:decimal)
where $x/price>30
return $x/title
as xs:decimal?
```

These expressions yield the same result.

XQuery Comparisons

General Comparisons: =, !=, <, <=, >, >=

```
$books > 10
```

Returns true if any q attributes have a value greater than 10

Value Comparisons: eq, ne, lt, le, gt, ge

```
bookstore //book/@q > 10
```

Returns true if there is only one q attribute returned by the expression and its value is greater than 10. If more than one 1 is returned, and error occurs

Examples of Function Calls

Example 1: In an element

```
<name> {upper-case($booktitle)} </name>
```

Example 2: In the predicate of a path expression

```
doc("books.xml")/ bookstore /book[ substring(1, 5) = 'Harry' ]
```

Example 3: In a let clause

```
let $name := (substring($booktitle, 1, 4))
```

A call to a function can appear where an expression may appear.

User-Defined Functions

If you cannot find the XQuery function you need, you can write your own. Functions can be defined in the query or in a separate library.

Syntax

```
declare function prefix: function_name( $parameter )
as return Datatype
{
...function code here...
}
```

Example: Declared in the Query

```
for $x in doc("books.xml")/bookstore/book
declare function local: min Price($p as xs:decimal)
where $x/price>30
return $x/title
as xs:decimal?

{
let $disc := ($p * $d) div 100
return ($p - $disc)
};
```

How to call the function

User-Defined Functions (cont)

```
<mi nPrice >{local:inPrice($book/price,$book/unt)} </inPrice>
```

Note:

Use the declare function keyword.

The name of the function must be prefixed.

The data type of the parameters are mostly the same as the data types defined in XML Schema.

The body of the function must be surrounded by curly braces.

XQuery Terminology

Nodes In XQuery there are 7 kinds: element, attribute, text, namespace, processing-instruction, comment, and document (root)

Atomic Values Atomic values are nodes with no children or parent

Items Items refer to nodes and atomic values

Parent Each element and attribute has one parent

Children Element nodes may have 0, 1, or more children.

Siblings Nodes that have the same parent

Ancestors A node's parent, parent's parent, etc.

Descendants A node's children, children's children, etc.

XQuery Conditional Expressions

If-Then-Else expressions are allowed in XQuery

```
for $x in doc("books.xml")/book
return if ($x/category="children")
then <child>{data($x/title)} </child>
else <adult>{data($x/title)} </adult>
```

Note: "if-then-else" syntax: parentheses around the if expression are required. else is required, but it can be just else ().

Returning HTML

```
This is o
for $x in doc("books.xml")/book
where $x/price>30
order by $x/title
return $x/title
```

Yields

```
<ul>
<li><title lang="en">Everyday Italia n</title> </li>
<li><title lang="en">Harry Potter </title> </li>
<li><title lang="en">Learning XML</title> </li>
<li><title lang="en">XQuery Kick Start</title> </li>
</ul>
```

```
=====
===
```

This

```
<ul>
{
for $x in doc("books.xml")/book
order by $x
return <li>{data($x)} </li>
}
</ul>
```

Yields

```
<ul>
<li>Everyday Italia n</li>
<li>Harry Potter </li>
<li>Learning XML</li>
<li>XQuery Kick Start</li>
</ul>
```

Note: To eliminate the title element and show only data inside the title element use data(\$x)

Adding Elements and Attributes to the Result

This

```
<ht ml>
<bo dy>
<h1 >Bo oks tor e</ h1>
<ul>
{
for $x in doc("bo oks.xml")/ boo kst ore /book
order by $x/title
return <li >{d ata ($x /ti tle)}. Category:
{data( $x/ @ca teg ory )}< /li>
}
</u l>
</b ody>
</h tml>
```

Yields

```
<ht ml>
<bo dy>
<h1 >Bo oks tor e</ h1>
<ul>
<li >Ev eryday Italian. Category: COOKIN G</ li>
<li >Harry Potter. Category: CHILDR EN< /li>
<li >Le arning XML. Category: WEB</l i>
<li >XQuery Kick Start. Category: WEB</l i>
</u l>
</b ody>
</h tml>
```

=====

This

```
<ht ml>
<bo dy>
<h1 >Bo oks tor e</ h1>
<ul>
{
```

Adding Elements and Attributes to the Result (cont)

```
> for $x in doc("books.xml")/bookstore/book
order by $x/title
return <li class="{data($x/@category)}">{data($x/title)}</li>
}
</ul>
</body>
</html>
Yields
<html>
<body>
<h1>Bookstore</h1>
<ul>
<li class="COOKING">Everyday Italian</li>
<li class="CHILDREN">Harry Potter</li>
<li class="WEB">Learning XML</li>
<li class="WEB">XQuery Kick Start</li>
</ul>
</body>
</html>
```
